75210 |             We use frameCount as a basis for the number of frames to read since that's what's being
75211 |             requested, however we still need to clamp it to whatever can fit in the cache.
75212 |
75213 |             This will also be used as the basis for determining how many input frames to read. This
> is

```

```

75214 |         not ideal because it can result in too many input frames being read which introduces
> latency.
75215 |         To solve this, nodes can implement an optional callback called
> onGetRequiredInputFrameCount
75216 |         which is used as hint to miniaudio as to how many input frames it needs to read at a
> time. This
75217 |         callback is completely optional, and if it's not set, miniaudio will assume
> `frameCount`.
75218 |
75219 |         This function will be called multiple times for each period of time, once for each
> output node.
75220 |         We cannot read from each input node each time this function is called. Instead we need
> to check
75221 |         whether or not this is first output bus to be read from for this time period, and if so,
> read
75222 |         from our input data.
75223 |
75224 |         To determine whether or not we're ready to read data, we check a flag. There will be one
> flag
75225 |         for each output. When the flag is set, it means data has been read previously and that
> we're
75226 |         ready to advance time forward for our input nodes by reading fresh data.

```

76721 |     while (totalFramesProcessedOut < frameCountOut) {
76722 |         /*
76723 |         We need to process in a specific order. We always do resampling first because it's likely
76724 |         we're going to be increasing the channel count after spatialization. Also, I want to do
76725 |         fading based on the output sample rate.
76726 |
76727 |         We'll first read into a buffer from the resampler. Then we'll do all processing that
76728 |         operates on the on the input channel count. We'll then get the spatializer to output to
76729 |         the output buffer and then do all effects from that point directly in the output buffer
76730 |         in-place.
76731 |
76732 |         Note that we're always running the resampler if pitching is enabled, even when the pitch
76733 |         is 1. If we try to be clever and skip resampling when the pitch is 1, we'll get a glitch
76734 |         when we move away from 1, back to 1, and then away from 1 again. We'll want to implement
76735 |         any pitch=1 optimizations in the resampler itself.
76736 |
76737 |         There's a small optimization here that we'll utilize since it might be a fairly common
76738 |         case. When the input and output channel counts are the same, we'll read straight into the
76739 |         output buffer from the resampler and do everything in-place.
