24474 |     I've had a report that GetCurrentPadding() is returning a frame count of 0 which is preventing
24475 |     higher level function calls from doing anything because it thinks nothing is available. I have
24476 |     taken a look at the documentation and it looks like this is unnecessary in exclusive mode.
24477 |
24478 |     From Microsoft's documentation:
24479 |

```

```

24480 |         For an exclusive-mode rendering or capture stream that was initialized with the
24481 |         AUDCLNT_STREAMFLAGS_EVENTCALLBACK flag, the client typically has no use for the padding
24482 |         value reported by GetCurrentPadding. Instead, the client accesses an entire buffer during
24483 |         each processing pass.
24484 |
24485 |         Considering this, I'm going to skip GetCurrentPadding() for exclusive mode and just report the
24486 |         entire buffer. This depends on the caller making sure they wait on the event handler.
24487 |         */

25148 |
25149 | /*
25150 | Annoyingly, WASAPI does not allow you to release an IAudioClient object from a different thread
25151 | than the one that retrieved it with GetService(). This can result in a deadlock in two
25152 | situations:
25153 |
25154 | 1) When calling ma_device_uninit() from a different thread to ma_device_init(); and

```

```

25155 |         2) When uninitializing and reinitializing the internal IAudioClient object in response to
25156 |             automatic stream routing.
25157 |
25158 |         We could define ma_device_uninit() such that it must be called on the same thread as
25159 |         ma_device_init(). We could also just not release the IAudioClient when performing automatic
25160 |         stream routing to avoid the deadlock. Neither of these are acceptable solutions in my view so
25161 |         we're going to have to work around this with a worker thread. This is not ideal, but I can't
25162 |         think of a better way to do this.
25163 |
25164 |         More information about this can be found here:
25165 |
25166 |         > https://docs.microsoft.com/en-us/windows/win32/api/audioclient/nn-audioclient-iaudiorenderclient
25167 |
25168 |         Note this section:
25169 |
25170 |         When releasing an IAudioRenderClient interface instance, the client must call the
25171 |         > interface's
25172 |         Release method from the same thread as the call to IAudioClient::GetService that created the
25173 |         object.
25174 |         */

30260 | PulseAudio Backend
30261 |
30262 | *****/
30263 | #ifdef MA_HAS_PULSEAUDIO
30264 | /*
30265 | The PulseAudio API, along with Apple's Core Audio, is the worst of the mainstream audio APIs. This
> is a brief description of what's going on
30266 | in the PulseAudio backend. I apologize if this gets a bit ranty for your liking - you might want to
> skip this discussion.

```

```

30267 |
30268 | PulseAudio has something they call the "Simple API", which unfortunately isn't suitable for
> miniaudio. I've not seen anywhere where it
30269 | allows you to enumerate over devices, nor does it seem to support the ability to stop and start
> streams. Looking at the documentation, it
30270 | appears as though the stream is constantly running and you prevent sound from being emitted or
> captured by simply not calling the read or
30271 | write functions. This is not a professional solution as it would be much better to *actually* stop
> the underlying stream. Perhaps the
30272 | simple API has some smarts to do this automatically, but I'm not sure. Another limitation with the
> simple API is that it seems inefficient
30273 | when you want to have multiple streams to a single context. For these reasons, miniaudio is not
> using the simple API.
30274 |
30275 | Since we're not using the simple API, we're left with the asynchronous API as our only other option.
> And boy, is this where it starts to
30276 | get fun, and I don't mean that in a good way...
30277 |
30278 | The problems start with the very name of the API - "asynchronous". Yes, this is an asynchronous
> oriented API which means your commands
30279 | don't immediately take effect. You instead need to issue your commands, and then wait for them to
> complete. The waiting mechanism is
30280 | enabled through the use of a "main loop". In the asynchronous API you cannot get away from the main
> loop, and the main loop is where almost
30281 | all of PulseAudio's problems stem from.
30282 |
30283 | When you first initialize PulseAudio you need an object referred to as "main loop". You can
> implement this yourself by defining your own
30284 | vtable, but it's much easier to just use one of the built-in main loop implementations. There's two
> generic implementations called
30285 | pa_mainloop and pa_threaded_mainloop, and another implementation specific to GLib called
> pa_glib_mainloop. We're using pa_threaded_mainloop
30286 | because it simplifies management of the worker thread. The idea of the main loop object is pretty
> self explanatory - you're supposed to use
30287 | it to implement a worker thread which runs in a loop. The main loop is where operations are actually
> executed.
30288 |
30289 | To initialize the main loop, you just use `pa_threaded_mainloop_new()`. This is the first function
> you'll call. You can then get a pointer
30290 | to the vtable with `pa_threaded_mainloop_get_api()` (the main loop vtable is called
> `pa_mainloop_api`). Again, you can bypass the threaded
30291 | main loop object entirely and just implement `pa_mainloop_api` directly, but there's no need for it
> unless you're doing something extremely
30292 | specialized such as if you want to integrate it into your application's existing main loop
> infrastructure.
30293 |
30294 | (EDIT 2021-01-26: miniaudio is no longer using `pa_threaded_mainloop` due to this issue:
> https://github.com/mackron/miniaudio/issues/262.
30295 | It is now using `pa_mainloop` which turns out to be a simpler solution anyway. The rest of this rant
> still applies, however.)
30296 |
30297 | Once you have your main loop vtable (the `pa_mainloop_api` object) you can create the PulseAudio
> context. This is very similar to
30298 | miniaudio's context and they map to each other quite well. You have one context to many streams,
> which is basically the same as miniaudio's
30299 | one `ma_context` to many `ma_device`s. Here's where it starts to get annoying, however. When you
> first create the PulseAudio context, which
30300 | is done with `pa_context_new()`, it's not actually connected to anything. When you connect, you call
> `pa_context_connect()`. However, if
30301 | you remember, PulseAudio is an asynchronous API. That means you cannot just assume the context is
> connected after `pa_context_connect()`
30302 | has returned. You instead need to wait for it to connect. To do this, you need to either wait for a
> callback to get fired, which you can
30303 | set with `pa_context_set_state_callback()`, or you can continuously poll the context's state. Either
> way, you need to run this in a loop.
30304 | All objects from here out are created from the context, and, I believe, you can't be creating these
> objects until the context is connected.
30305 | This waiting loop is therefore unavoidable. In order for the waiting to ever complete, however, the
> main loop needs to be running. Before
30306 | attempting to connect the context, the main loop needs to be started with
> `pa_threaded_mainloop_start()`.
30307 |
30308 | The reason for this asynchronous design is to support cases where you're connecting to a remote
> server, say through a local network or an
30309 | internet connection. However, the *VAST* majority of cases don't involve this at all - they just
> connect to a local "server" running on the
30310 | host machine. The fact that this would be the default rather than making `pa_context_connect()`
> synchronous tends to boggle the mind.
30311 |

```

```

30312 | Once the context has been created and connected you can start creating a stream. A PulseAudio stream
> | is analogous to miniaudio's device.
30313 | The initialization of a stream is fairly standard - you configure some attributes (analogous to
> | miniaudio's device config) and then call
30314 | `pa_stream_new()` to actually create it. Here is where we start to get into "operations". When
> | configuring the stream, you can get
30315 | information about the source (such as sample format, sample rate, etc.), however it's not
> | synchronous. Instead, a `pa_operation` object
30316 | is returned from `pa_context_get_source_info_by_name()` (capture) or
> | `pa_context_get_sink_info_by_name()` (playback). Then, you need to
30317 | run a loop (again!) to wait for the operation to complete which you can determine via a callback or
> | polling, just like we did with the
30318 | context. Then, as an added bonus, you need to decrement the reference counter of the `pa_operation`
> | object to ensure memory is cleaned up.
30319 | All of that just to retrieve basic information about a device!
30320 |
30321 | Once the basic information about the device has been retrieved, miniaudio can now create the stream
> | with `ma_stream_new()`. Like the
30322 | context, this needs to be connected. But we need to be careful here, because we're now about to
> | introduce one of the most horrific design
30323 | choices in PulseAudio.
30324 |
30325 | PulseAudio allows you to specify a callback that is fired when data can be written to or read from a
> | stream. The language is important here
30326 | because PulseAudio takes it literally, specifically the "can be". You would think these callbacks
> | would be appropriate as the place for
30327 | writing and reading data to and from the stream, and that would be right, except when it's not. When
> | you initialize the stream, you can
30328 | set a flag that tells PulseAudio to not start the stream automatically. This is required because
> | miniaudio does not auto-start devices
30329 | straight after initialization - you need to call `ma_device_start()` manually. The problem is that
> | even when this flag is specified,
30330 | PulseAudio will immediately fire its write or read callback. This is *technically* correct (based on
> | the wording in the documentation)
30331 | because indeed, data *can* be written at this point. The problem is that it's not *practical*. It
> | makes sense that the write/read callback
30332 | would be where a program will want to write or read data to or from the stream, but when it's called
> | before the application has even
30333 | requested that the stream be started, it's just not practical because the program probably isn't
> | ready for any kind of data delivery at
30334 | that point (it may still need to load files or whatnot). Instead, this callback should only be fired
> | when the application requests the
30335 | stream be started which is how it works with literally *every* other callback-based audio API. Since
> | miniaudio forbids firing of the data
30336 | callback until the device has been started (as it should be with *all* callback based APIs), logic
> | needs to be added to ensure miniaudio
30337 | doesn't just blindly fire the application-defined data callback from within the PulseAudio callback
> | before the stream has actually been
30338 | started. The device state is used for this - if the state is anything other than
> | `ma_device_state_starting` or `ma_device_state_started`, the main data
30339 | callback is not fired.
30340 |
30341 | This, unfortunately, is not the end of the problems with the PulseAudio write callback. Any normal
> | callback based audio API will
30342 | continuously fire the callback at regular intervals based on the size of the internal buffer. This
> | will only ever be fired when the device
30343 | is running, and will be fired regardless of whether or not the user actually wrote anything to the
> | device/stream. This not the case in
30344 | PulseAudio. In PulseAudio, the data callback will *only* be called if you wrote something to it
> | previously. That means, if you don't call
30345 | `pa_stream_write()`, the callback will not get fired. On the surface you wouldn't think this would
> | matter because you should be always
30346 | writing data, and if you don't have anything to write, just write silence. That's fine until you
> | want to drain the stream. You see, if
30347 | you're continuously writing data to the stream, the stream will never get drained! That means in
> | order to drain the stream, you need to
30348 | *not* write data to it! But remember, when you don't write data to the stream, the callback won't
> | get fired again! Why is draining
30349 | important? Because that's how we've defined stopping to work in miniaudio. In miniaudio, stopping
> | the device requires it to be drained
30350 | before returning from ma_device_stop(). So we've stopped the device, which requires us to drain, but
> | draining requires us to *not* write
30351 | data to the stream (or else it won't ever complete draining), but not writing to the stream means
> | the callback won't get fired again!
30352 |
30353 | This becomes a problem when stopping and then restarting the device. When the device is stopped,
> | it's drained, which requires us to *not*
30354 | write anything to the stream. But then, since we didn't write anything to it, the write callback
> | will *never* get called again if we just

```

```

30355 | resume the stream naively. This means that starting the stream requires us to write data to the
> stream from outside the callback. This
30356 | disconnect is something PulseAudio has got seriously wrong - there should only ever be a single
> source of data delivery, that being the
30357 | callback. (I have tried using `pa_stream_flush()` to trigger the write callback to fire, but this
> just doesn't work for some reason.)
30358 |
30359 | Once you've created the stream, you need to connect it which involves the whole waiting procedure.
> This is the same process as the context,
30360 | only this time you'll poll for the state with `pa_stream_get_status()`. The starting and stopping of
> a streaming is referred to as
30361 | "corking" in PulseAudio. The analogy is corking a barrel. To start the stream, you uncork it, to
> stop it you cork it. Personally I think
30362 | it's silly - why would you not just call it "starting" and "stopping" like any other normal audio
> API? Anyway, the act of corking is, you
30363 | guessed it, asynchronous. This means you'll need our waiting loop as usual. Again, why this
> asynchronous design is the default is
30364 | absolutely beyond me. Would it really be that hard to just make it run synchronously?
30365 |
30366 | Teardown is pretty simple (what?!). It's just a matter of calling the relevant `_unref()` function
> on each object in reverse order that
30367 | they were initialized in.
30368 |
30369 | That's about it from the PulseAudio side. A bit ranty, I know, but they really need to fix that main
> loop and callback system. They're
30370 | embarrassingly unpractical. The main loop thing is an easy fix - have synchronous versions of all
> APIs. If an application wants these to
30371 | run asynchronously, they can execute them in a separate thread themselves. The desire to run these
> asynchronously is such a niche
30372 | requirement - it makes no sense to make it the default. The stream write callback needs to be
> change, or an alternative provided, that is
30373 | constantly fired, regardless of whether or not `pa_stream_write()` has been called, and it needs to
> take a pointer to a buffer as a
30374 | parameter which the program just writes to directly rather than having to call
> `pa_stream_writable_size()` and `pa_stream_write()`. These
30375 | changes alone will change PulseAudio from one of the worst audio APIs to one of the best.

33542 | Core Audio
33543 |
33544 | So far, Core Audio has been the worst backend to work with due to being both unintuitive and having

```

```

> almost no documentation
33545 | apart from comments in the headers (which admittedly are quite good). For my own purposes, and for
> anybody out there whose
33546 | needing to figure out how this darn thing works, I'm going to outline a few things here.
33547 |
33548 | Since miniaudio is a fairly low-level API, one of the things it needs is control over specific
> devices, and it needs to be
33549 | able to identify whether or not it can be used as playback and/or capture. The AudioObject API is
> the only one I've seen
33550 | that supports this level of detail. There was some public domain sample code I stumbled across that
> used the AudioComponent
33551 | and AudioUnit APIs, but I couldn't see anything that gave low-level control over device selection
> and capabilities (the
33552 | distinction between playback and capture in particular). Therefore, miniaudio is using the
> AudioObject API.
33553 |
33554 | Most (all?) functions in the AudioObject API take a AudioObjectID as its input. This is the device
> identifier. When
33555 | retrieving global information, such as the device list, you use kAudioObjectSystemObject. When
> retrieving device-specific
33556 | data, you pass in the ID for that device. In order to retrieve device-specific IDs you need to
> enumerate over each of the
33557 | devices. This is done using the AudioObjectGetPropertyDataSize() and AudioObjectGetPropertyData()
> APIs which seem to be
33558 | the central APIs for retrieving information about the system and specific devices.
33559 |
33560 | To use the AudioObjectGetPropertyData() API you need to use the notion of a property address. A
> property address is a
33561 | structure with three variables and is used to identify which property you are getting or setting.
> The first is the "selector"
33562 | which is basically the specific property that you're wanting to retrieve or set. The second is the
> "scope", which is
33563 | typically set to kAudioObjectPropertyScopeGlobal, kAudioObjectPropertyScopeInput for input-specific
> properties and
33564 | kAudioObjectPropertyScopeOutput for output-specific properties. The last is the "element" which is
> always set to
33565 | kAudioObjectPropertyElementMain in miniaudio's case. I don't know of any cases where this would be
> set to anything different.
33566 |
33567 | Back to the earlier issue of device retrieval, you first use the AudioObjectGetPropertyDataSize()
> API to retrieve the size
33568 | of the raw data which is just a list of AudioDeviceID's. You use the kAudioObjectSystemObject
> AudioObjectID, and a property
33569 | address with the kAudioHardwarePropertyDevices selector and the kAudioObjectPropertyScopeGlobal
> scope. Once you have the
33570 | size, allocate a block of memory of that size and then call AudioObjectGetPropertyData(). The data
> is just a list of
33571 | AudioDeviceID's so just do "dataSize/sizeof(AudioDeviceID)" to know the device count.
33572 | */

35909 |             Technical Note TN2091: Device input using the HAL Output Audio Unit
35910 |             https://developer.apple.com/library/archive/technotes/tn2091/\_index.html
35911 |
35912 |             This documentation says the following:
35913 |
35914 |             The internal AudioConverter can handle any *simple* conversion. Typically, this means
> that a client can specify ANY
35915 |             variant of the PCM formats. Consequently, the device's sample rate should match the
> desired sample rate. If sample rate
35916 |             conversion is needed, it can be accomplished by buffering the input and converting the
> data on a separate thread with
35917 |             another AudioConverter.
35918 |
35919 |             The important part here is the mention that it can handle *simple* conversions, which does
> *not* include sample rate. We
35920 |             therefore want to ensure the sample rate stays consistent. This document is specifically for
> input, but I'm going to play it
35921 |             safe and apply the same rule to output as well.
35922 |
35923 |             I have tried going against the documentation by setting the sample rate anyway, but this
> just results in AudioUnitRender()
35924 |             returning a result code of -10863. I have also tried changing the format directly on the
> input scope on the input bus, but
35925 |             this just results in `ca_require: IsStreamFormatWritable(inScope, inElement) NotWritable`
> when trying to set the format.
35926 |
35927 |             Something that does seem to work, however, has been setting the nominal sample rate on the
> device object. The problem with
35928 |             this, however, is that it actually changes the sample rate at the operating system level and
> not just the application. This
35929 |             could be intrusive to the user, however, so I don't think it's wise to make this the
> default. Instead I'm making this a
35930 |             configuration option. When the `coreaudio.allowNominalSampleRateChange` config option is set
> to true, changing the sample
35931 |             rate will be allowed. Otherwise it'll be fixed to the current sample rate. To check the
> system-defined sample rate, run
35932 |             the Audio MIDI Setup program that comes installed on macOS and observe how the sample rate
> changes as the sample rate is
35933 |             changed by miniaudio.
35934 |             */

38935 | Note on Starting and Stopping
38936 | =====
38937 | In the past I was using SNDCTL_DSP_HALT to stop the device, however this results in issues when
38938 | trying to resume the device again. If we use SNDCTL_DSP_HALT, the next write() or read() will
38939 | fail. Instead what we need to do is just not write or read to and from the device when the
38940 | device is not running.
38941 |
38942 | As a result, both the start and stop functions for OSS are just empty stubs. The starting and
38943 | stopping logic is handled by ma_device_write_oss() and ma_device_read_oss(). These will check
38944 | the device state, and if the device is stopped they will simply not do any kind of processing.
38945 |
38946 | The downside to this technique is that I've noticed a fairly lengthy delay in stopping the
38947 | device, up to a second. This is on a virtual machine, and as such might just be due to the
38948 | virtual drivers, but I'm not fully sure. I am not sure how to work around this problem so for
38949 | the moment that's just how it's going to have to be.
38950 |
38951 | When starting the device, OSS will automatically start it when write() or read() is called.

42613 |
42614 |     If the device is doing playback (ma_device_type_playback or ma_device_type_duplex), there's
42615 |     a couple of situations where we'll need a heap allocated cache.
42616 |
42617 |     The first is a duplex device for backends that use a callback for data delivery. The reason
42618 |     this is needed is that the input stage needs to have a buffer to place the input data while it
42619 |     waits for the playback stage, after which the miniaudio data callback will get fired. This is
42620 |     not needed for backends that use a blocking API because miniaudio manages temporary buffers on
42621 |     the stack to achieve this.
42622 |
42623 |     The other situation is when the data converter does not have the ability to query the number
42624 |     of input frames that are required in order to process a given number of output frames. When
42625 |     performing data conversion, it's useful if miniaudio know exactly how many frames it needs

```

```

42626 | from the client in order to generate a given number of output frames. This way, only exactly
42627 | the number of frames are needed to be read from the client which means no cache is necessary.
42628 | On the other hand, if miniaudio doesn't know how many frames to read, it is forced to read
42629 | in fixed sized chunks and then cache any residual unused input frames, those of which will be
42630 | processed at a later stage.
42631 | */

52555 |                 }
52556 |
52557 |                 /*
52558 |                 In my testing, if the panning effect is too aggressive it makes spatialization feel
> uncomfortable.
52559 |                 The "dMin" variable below is used to control the aggressiveness of the panning
> effect. When set to
52560 |                 0, panning will be most extreme and any sounds that are positioned on the opposite
> side of the
52561 |                 speaker will be completely silent from that speaker. Not only does this feel
> uncomfortable, it
52562 |                 doesn't even remotely represent the real world at all because sounds that come from
> your right side
52563 |                 are still clearly audible from your left side. Setting "dMin" to 1 will result in no
> panning at
52564 |                 all, which is also not ideal. By setting it to something greater than 0, the
> spatialization effect
52565 |                 becomes much less dramatic and a lot more bearable.
52566 |
52567 |                 Summary: 0 = more extreme panning; 1 = no panning.
52568 |                 */
52569 |                 dMin = pSpatializer->minSpatializationChannelGain;
52570 |
52571 |                 /*

```

```

52572 |           At this point, "d" will be positive if the sound is on the same side as the channel
> and negative if
52573 |           it's on the opposite side. It will be in the range of -1..1. There's two ways I can
> think of to
52574 |           calculate a panning value. The first is to simply convert it to 0..1, however this
> has a problem
52575 |           which I'm not entirely happy with. Considering a stereo system, when a sound is
> positioned right
52576 |           in front of the listener it'll result in each speaker getting a gain of 0.5. I don't
> know if I like
52577 |           the idea of having a scaling factor of 0.5 being applied to a sound when it's
> sitting right in front
52578 |           of the listener. I would intuitively expect that to be played at full volume, or
> close to it.
52579 |
52580 |           The second idea I think of is to only apply a reduction in gain when the sound is on
> the opposite
52581 |           side of the speaker. That is, reduce the gain only when the dot product is negative.
> The problem
52582 |           with this is that there will not be any attenuation as the sound sweeps around the
> 180 degrees
52583 |           where the dot product is positive. The idea with this option is that you leave the
> gain at 1 when
52584 |           the sound is being played on the same side as the speaker and then you just reduce
> the volume when
52585 |           the sound is on the other side.
52586 |
52587 |           The summarize, I think the first option should give a better sense of
> spatialization, but the second
52588 |           option is better for preserving the sound's power.
52589 |
52590 |           UPDATE: In my testing, I find the first option to sound better. You can feel the
> sense of space a
52591 |           bit better, but you can also hear the reduction in volume when it's right in front.
52592 |           */
52593 |           #if 1
52594 |           {
52595 |               /*
52596 |               Scale the dot product from -1..1 to 0..1. Will result in a sound directly in
> front losing power
52597 |               by being played at 0.5 gain.
52598 |               */

54347 |
54348 | static float ma_calculate_channel_position_rectangular_weight(ma_channel channelPositionA,
> ma_channel channelPositionB)
54349 | {
54350 |     /*
54351 |     Imagine the following simplified example: You have a single input speaker which is the
> front/left speaker which you want to convert to
54352 |     the following output configuration:
54353 |
54354 |     - front/left
54355 |     - side/left
54356 |     - back/left
54357 |
54358 |     The front/left output is easy - it the same speaker position so it receives the full
> contribution of the front/left input. The amount
54359 |     of contribution to apply to the side/left and back/left speakers, however, is a bit more
> complicated.
54360 |
54361 |     Imagine the front/left speaker as emitting audio from two planes - the front plane and the left
> plane. You can think of the front/left
54362 |     speaker emitting half of its total volume from the front, and the other half from the left.
> Since part of its volume is being emitted
54363 |     from the left side, and the side/left and back/left channels also emit audio from the left
> plane, one would expect that they would
54364 |     receive some amount of contribution from front/left speaker. The amount of contribution depends
> on how many planes are shared between
54365 |     the two speakers. Note that in the examples below I've added a top/front/left speaker as an
> example just to show how the math works
54366 |     across 3 spatial dimensions.
54367 |
54368 |     The first thing to do is figure out how each speaker's volume is spread over each of plane:
54369 |     - front/left:    2 planes (front and left)    = 1/2 = half its total volume on each plane
54370 |     - side/left:     1 plane (left only)          = 1/1 = entire volume from left plane
54371 |     - back/left:     2 planes (back and left)      = 1/2 = half its total volume on each plane
54372 |     - top/front/left: 3 planes (top, front and left) = 1/3 = one third its total volume on each
> plane
54373 |
54374 |     The amount of volume each channel contributes to each of its planes is what controls how much it
> is willing to given and take to other
54375 |     channels on the same plane. The volume that is willing to the given by one channel is multiplied
> by the volume that is willing to be
54376 |     taken by the other to produce the final contribution.
54377 |     */

```
